

Section 3: The Istanbul Mayoral Election

Milan Svolik

4/20/2023

Load the data

```
load("data/df_2019istanbul_results.RData")
```

Summarize the number of districts, neighborhoods, and ballot boxes

```
df_results %>%  
  distinct(district_id) %>%  
  count()
```

```
## # A tibble: 1 x 1  
##       n  
##   <int>  
## 1    39
```

```
df_results %>%  
  distinct(neighborhood_id) %>%  
  count()
```

```
## # A tibble: 1 x 1  
##       n  
##   <int>  
## 1   956
```

```
df_results %>%  
  distinct(box_id) %>%  
  count()
```

```
## # A tibble: 1 x 1  
##       n  
##   <int>  
## 1 31101
```

Aggregate shifts

- Third-party voters are treated as abstaining

```
df_results %>%  
  mutate(  
    ABS_march = ABS_march + THIRD_march,  
    ABS_june = ABS_june + THIRD_june  
  ) %>%  
  summarize(AKP_march=sum(AKP_march), CHP_march=sum(CHP_march), ABS_march=sum(ABS_march), AKP_june=sum(  
  mutate(
```

```

REG_march = AKP_march + CHP_march + ABS_march,
AKP_share_march = AKP_march/REG_march,
CHP_share_march = CHP_march/REG_march,
ABS_share_march = ABS_march/REG_march,
REG_june = AKP_june + CHP_june + ABS_june,
AKP_share_june = AKP_june/REG_june,
CHP_share_june = CHP_june/REG_june,
ABS_share_june = ABS_june/REG_june,
AKP_share_shift = AKP_share_june - AKP_share_march,
CHP_share_shift = CHP_share_june - CHP_share_march,
ABS_share_shift = ABS_share_june - ABS_share_march
) %>%
select(AKP_share_shift, CHP_share_shift, ABS_share_shift) %>%
round(4)

```

```

## # A tibble: 1 x 3
##   AKP_share_shift CHP_share_shift ABS_share_shift
##   <dbl>          <dbl>          <dbl>
## 1      -0.0208      0.0542      -0.0334

```

Figure 2

- ELECTION RESULTS: SHIFTS IN THE AKP TWO-PARTY VOTE SHARE, THE AKP VOTE, CHP VOTE, AND ABSTENTION BETWEEN MARCH AND JUNE 2019

Prepare the plot data

```

# CHECK ON THE SHARE OF THIRD-PARTY VOTERS
df_results %>%
  mutate(across(AKP_march:THIRD_june, sum)) %>%
  slice(1) %>%
  mutate(
    THIRD_share_march = THIRD_march/(AKP_march + CHP_march + ABS_march + THIRD_march),
    THIRD_share_june = THIRD_june/(AKP_june + CHP_june + ABS_june + THIRD_june)) %>%
  select(starts_with("THIRD"))

```

```

## # A tibble: 1 x 4
##   THIRD_march THIRD_june THIRD_share_march THIRD_share_june
##   <dbl>      <dbl>          <dbl>          <dbl>
## 1      223657      68318          0.0212          0.00647

```

```

# TREAT THIRD-PARTY VOTERS AS ABSTAINERS
df_results <- df_results %>%
  mutate(
    ABS_march = ABS_march + THIRD_march,
    ABS_june = ABS_june + THIRD_june
  ) %>%
  select(-THIRD_march, -THIRD_june)

```

AGGREGATE THE RESULTS AT THE NEIGHBORHOOD LEVEL

```

df_results_neighbourhood <- df_results %>%
  group_by(district_id, district_name, neighborhood_id, neighborhood_name) %>%

```

Alternative plot: Bootstrap the CIs for Figure 2

- Hierarchical bootstrap (at the level of neighborhoods): mimic the data-generating process (and any dependence within neighborhoods):
 - First, draw neighborhoods (with replacement)
 - Second, from each drawn neighborhood, draw ballot boxes from that neighborhood (with replacement)
 - Third, compute the statistic of interest
 - Repeats boot_rep times

```
df_boot <- df_results

# NUMBER OF BOOTSTRAP DRAWS
boot_rep <- 10000

# NUMBER OF NEIGHBORHOODS
neighborhood_index <- unique(df_results$neighborhood_id)
length(neighborhood_index)

# A DF FOR THE BOOTSTRAPPED STATISTIC
df_means <- c()
```

```

for (i in 1:boot_rep) {
  # SAMPLE THE NEIGHBORHOOD IDS
  boot_index_neighborhood <- sample(neighborhood_index, replace = TRUE)

  # THIS WILL BE THE DF OF BOOTSTRAPPED NEIGHBORHOODS
  df_neighborhood_boot <- c()
  for (j in 1:length(boot_index_neighborhood)) {

    # FILTER OUT NEIGHBORHOOD j
    df_neighborhood_j <- df_boot %>% filter(neighborhood_id == boot_index_neighborhood[j])

    # SAMPLE BOXES FROM NEIGHBORHOOD j
    box_length <- nrow(df_neighborhood_j)
    boot_index_box <- sample.int(box_length, replace = TRUE)
    df_boot_j <- df_neighborhood_j[boot_index_box, ]

```

SIMULATE THE NULL HYPOTHESIS

- Take the March fraction of citizens that voted for the AKP, the CHP, and abstained as the respective outcome probabilities under the null hypothesis
- Draw a large number of draws from the multinomial distribution for each neighborhood
- This simulation accounts for:
 - differences in neighborhood size: the same percentage shift in an outcome is less likely to occur by chance in neighborhoods with a larger number of registered voters
 - the fact that a negative correlation between shifts in any two outcomes arises mechanically because the number of registered voters is constant across the two elections

```

# A FUNCTION THAT RETURNS THE PERCENTILE OF THE VALUE x IN THE EMPIRICAL DISTRIBUTION OF sample
centile <- function(sample, x) {
  ecdf(sample)(x)
}
